In the past 50 years, the range of the nine-banded armadillo (*Dasypus novemcinctus*) in the southern United States has been rapidly expanding. As their range expands, armadillos increasingly come into conflict with suburban landowners. When foraging, armadillos often uproot ornamental plants. Their rooting activity also damages gardens, lawns, and flower beds. Their burrowing can damage tree roots and building foundations. Most armadillo damage is a result of their feeding habits. Armadillos dig shallow holes, 1-3 inches deep and 3-5 inches long, as they search for soil invertebrates.

A recent survey of Georgia Cooperative Extension Agents conducted by the Warnell School of Forestry and Natural Resources found that 57.8% of all county agents reported receiving complaints or requests for information on armadillos. Armadillo related inquiries made up 9.5% all inquiries for all county agents across the state, behind only white-tail deer (*Odocoileus virginianus*; 19.1% of all inquiries) and wild pigs (*Sus scrofa*; 11.5% of all inquiries).

Armadillos are often assumed to destroy nests of ground-nesting birds. Armadillo diets have been studied in several states including Alabama, Arkansas, Georgia, Florida, Louisiana, and Texas. According to these studies, vertebrate matter, especially bird eggs, made up a minor portion of their diet. The armadillo’s diet often consists of more than 90% insects, grubs and earthworms. Based on these studies, it seems that claims of armadillos being significant nest predators are unfounded.

However, some authors have warned that armadillos merely break eggs open and lick out the contents. When this happens, little evidence remains in their stomachs, making detection of egg predation using stomach content analysis almost impossible. Using miniature video-surveillance cameras to monitor quail nests, at least one study at Tall Timbers Research Station in Florida has documented this behavior in wild armadillos. This study found that armadillos may be a more significant quail predator than previously accepted. Armadillos were responsible for destroying up to 26% of all quail nests.

Armadillos are not protected under Georgia wildlife regulations (DNR website [www.georgiawildlife.com](http://www.georgiawildlife.com)) and may be hunted or trapped year round without limit. Removal by shooting can be an effective control method. However, this may not be a safe or desirable option for the suburban
landowner. In many cases, suburban landowners would rather have animals trapped and relocated. Other control methods are available, such as habitat modification and exclusion, but these methods are often impractical over a large area, expensive, or ineffective. Our objective was to test several different lures or baits for live-trapping nine-banded armadillos. We used cage traps hoping they could be a practical alternative to lethal removal for suburban landowners.

**Methods**

We trapped armadillos, using 10 x 12 x 32-inch Tomahawk wire cage traps, from April to July 2004 at the Joseph W. Jones Ecological Research Center in Newton, Georgia. Traps were placed in areas with abundant armadillo sign. Since we were primarily interested in evaluating the attractants we avoided placing traps directly over burrows, where armadillos may be forced into traps.

In addition, we tested two types of unbaited traps: (1) an unbaited trap with “wings” consisting of two 6 feet long 2-inch x 6-inch boards attached at both side of one entrance to the trap to funnel the armadillo into the trap (see Figure 1), and (2) an unbaited trap without wings.

**Results**

In trapping studies, scientists compare data by calculating an index called trap-nights. One trap night equals 1 trap set for one night. Ten trap-nights equal 1 trap set for ten nights or ten traps set for one night.

In our study, we had 1,332 trap nights. We captured only 10 armadillos or an average of one armadillo every 132 trap nights. This number is quite low. Of the 11 attractants we evaluated, most of them (night crawlers, chicken feed, whole eggs, bananas, marshmallows, sardines, and vanilla wafers) had 0 captures. Table 1 shows the results of the 4 remaining

We tested the effectiveness of several baits and lures, including:

- Live night crawlers
- Live crickets
- Rotten chicken feed
- Whole eggs
- Rotten eggs
- Bananas
- Marshmallows
- Sardines
- Vanilla wafers
- Moistened soil
- “Armor plate” a commercially available lure

attractants. Capture success was too low for any meaningful statistical comparisons of attractants. However, when all baited traps (63% of trap-nights) were compared with the unbaited traps (37% of trap-nights), there was no significant difference in capture success (Figure 2). Only four armadillos were captured in traps with baits or lures. Six armadillo were captured in unbaited traps. Of these six, four were caught in unbaited traps with wings.

**Discussion**

Given that capture success was quite low, it is unlikely that trapping is an effective method of quickly reducing local armadillo populations. Until an effective attractant can be found, lethal removal by shooting remains the most effective solution. If live-trapping and relocation are chosen as control measures, however, the use of any of the attractants tested is unnecessary. Armadillos in this study were just as likely to enter a baited trap as an unbaited trap. It is likely that the armadillos we did capture randomly walked into the traps and were not necessarily attracted.

This suggests that if armadillos are to be captured, trap placement is much more important than attractant selection. Homeowners and others attempting to live trap armadillos should carefully select a trapping location. It is likely that a trap (even one without bait) with wings placed near an active burrow will be the most effective method for capturing individual nuisance animals. Homeowners and others can place traps near natural barriers or fences such as the wall of patios, edge of buildings, or landscaping features; or near natural barriers such as fallen trees. The use of baits and attractants does not appear to increase trap success.
